Methodology

The New York Times/Siena College survey of 849 registered voters nationwide was conducted in English and Spanish on landline and cellular telephones from July 5 to July 7, 2022.

The survey is a response-rate adjusted stratified sample of active registered voters on the L2 voter file. The probability of selection was equal to the reciprocal of the proportion of registrants within a stratum expected to participate in the survey, based on telephone coverage and the modeled probability of a completed interview.

The survey was fielded by the Siena College Research Institute and ReconMR. The interviewer asked for the person listed on the voter file and the interview was terminated if the listed person was not available. Overall, 63 percent of respondents were reached on cellular telephones.

Stratified quota sampling was conducted within the interaction of party, race and region. The first-stage weight adjusted for unequal probability of selection, ensuring that respondents from each stratum represented the appropriate share of the sample. Next, the samples were rake weighted using the R survey package to match targets for the registered voter population by age, race, party, gender, education, region, vote history, home ownership, marital status and home value.

Voter file data was used for weighting, with two exceptions. First, self-reported age was weighted to match targets from the voter file, except when the respondent refused to provide it. Second, self-reported education was weighted to match targets from Census-based estimates.

The population parameter for self-reported education was based on a model of voter registration in the Voting and Registration Supplement to the November 2020 Current Population Survey as a function of demographic characteristics available in the 2020 one-year American Community Survey. The C.P.S.-based estimates were applied to the A.C.S. adult citizen non-institutionalized civilian population and adjusted to match the estimated number of registered voters by state.

The estimated number of registered voters by state is based on the status of the registrant and a model of turnout in past elections. All "active" registered voters on the L2 voter file are presumed to be current registrants. The probability that an "inactive" voter remains a current registrant is based on the turnout among inactive voters in recent elections in a state, controlling for the person's record of voting: If inactive voters are 25 percent as likely to participate as active voters with a similar history of voting, then it is assumed that 25 percent of inactive voters remain registered in the state.

The survey's margin of sampling error is +/- 4.1 percentage points. It accounts for the survey's design effect of 1.46, a measure of the loss of statistical power due to weighting.
